CP Violation and Flavor Mixing

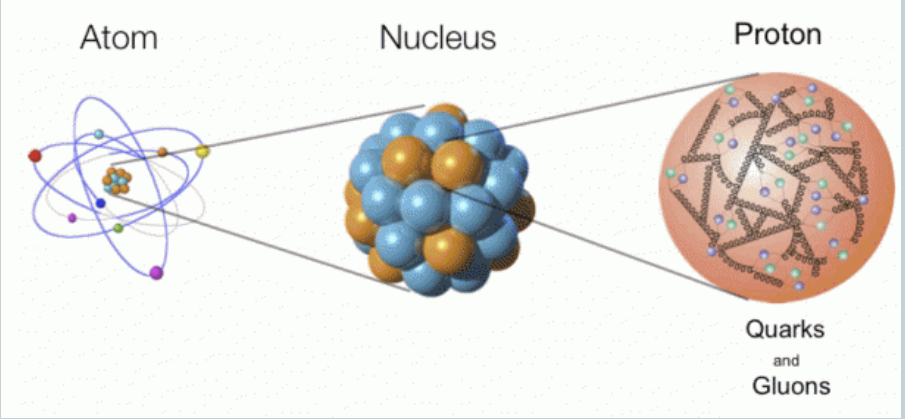
COLIN GLEASON

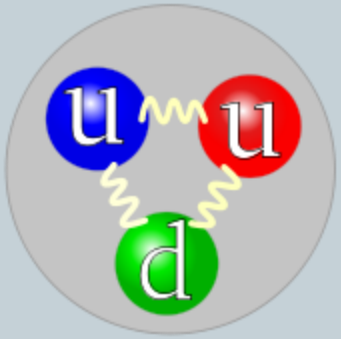
Outline

- Introduction to the Standard Model and CP violation
- Brief history of Particle Physics
- Work of Kobayashi
- Experimental Confirmation
- Lepton Flavor Mixing

Introduction

- Matter
  - e^- , p^+ , n
- Standard Model
  - 6 quarks, six leptons, fundamental interactions
- Comprehensive model for the elementary interactions of particle physics



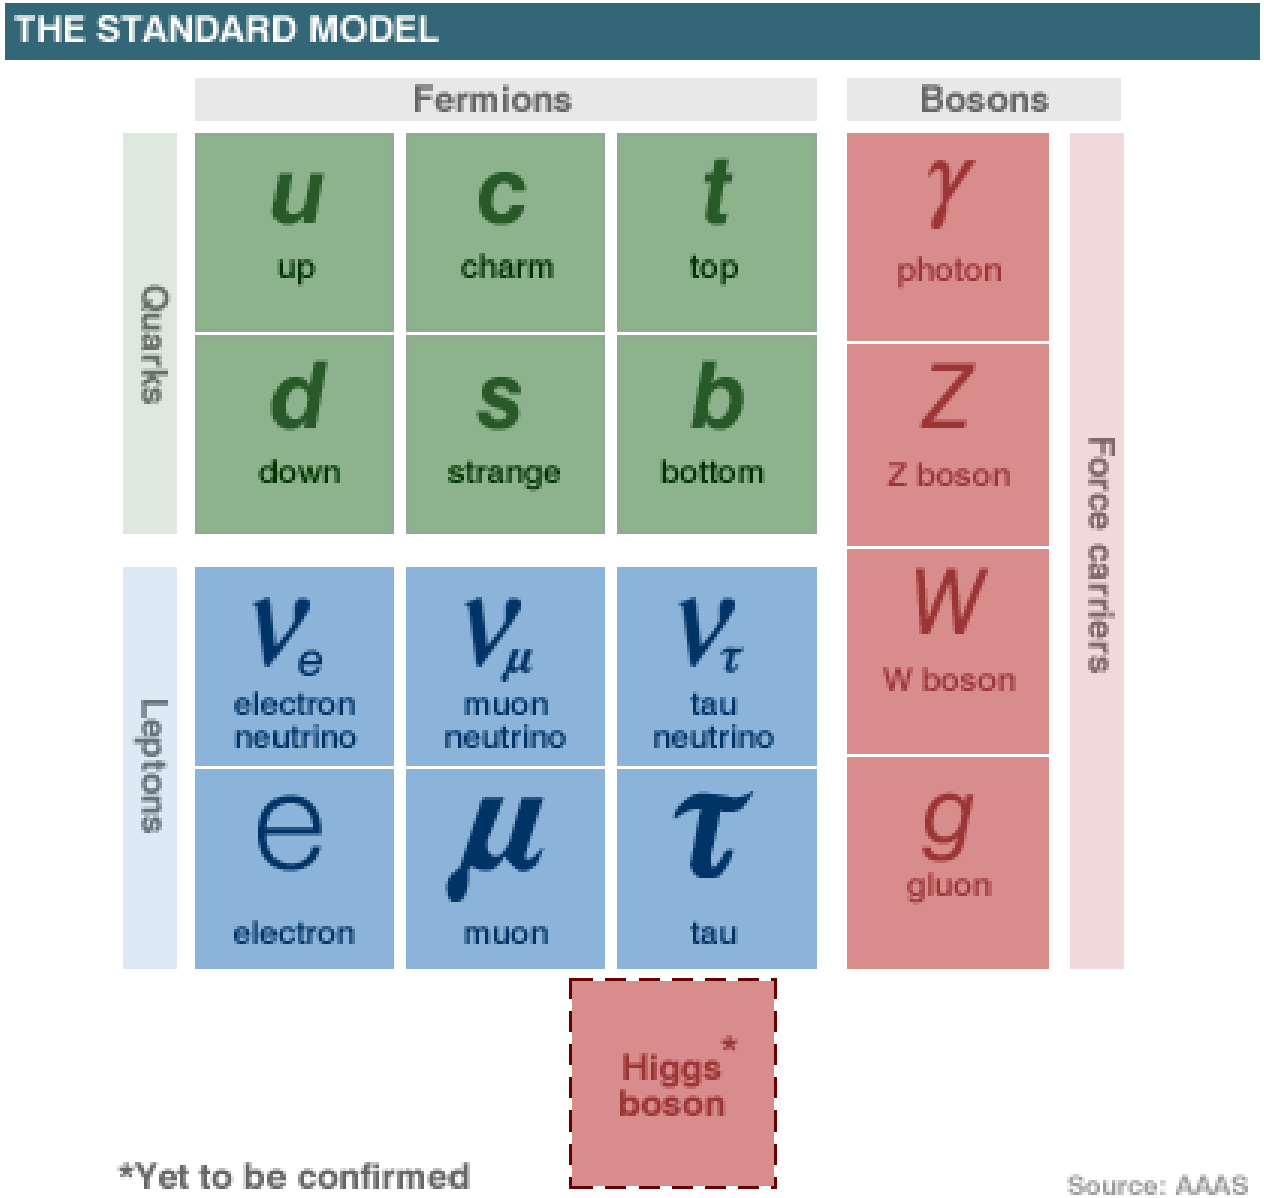


Standard Model

-Established in the 1970's

- Describes how particles interact via the strong and electroweak forces

- Does not incorporate general relativity and dark matter

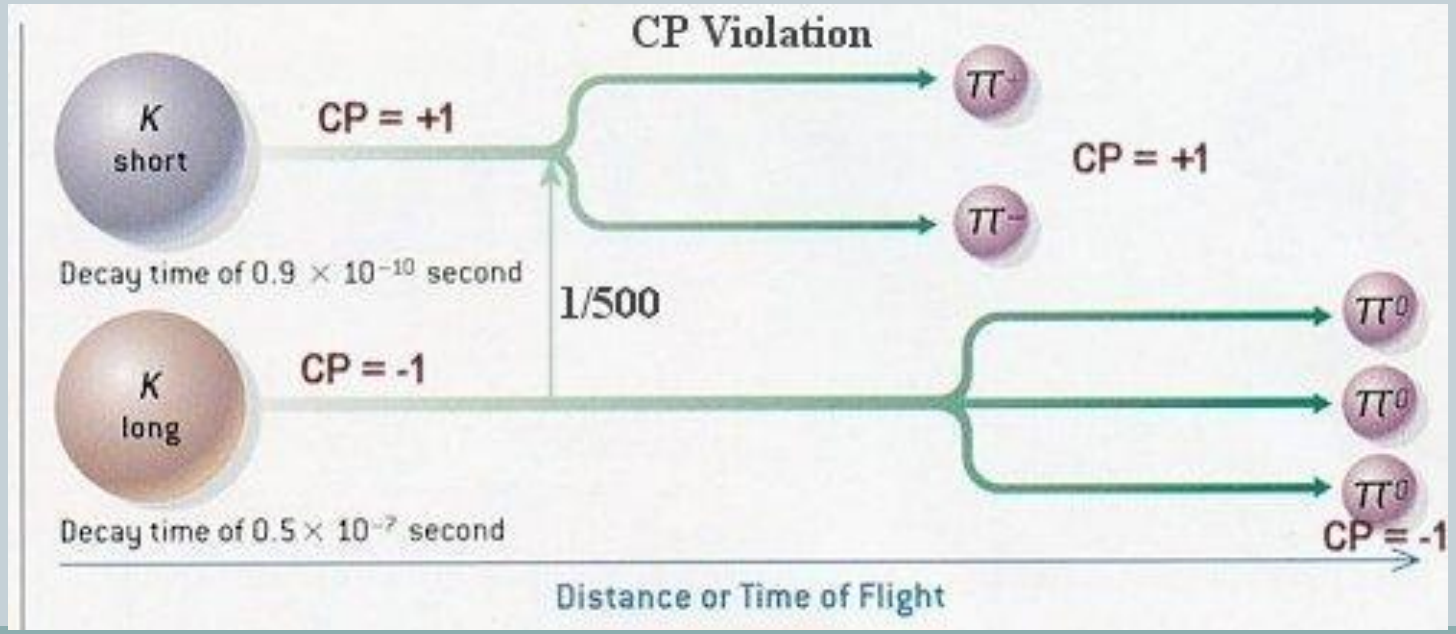


CP Violation

- CP violation is the violation of conservation laws associated with charge and parity
  - Indicates a fundamental difference between particles and their anti particles
  - May explain why there is more matter than anti-matter in the universe
- Cronin and Fitch discovered it in 1964 by observing the decay times of the K^0 meson
  - A K^0 particle will either decay into 2 pions (short lived) or 3 pions (long lived)
    - After enough time, all the decays should be long lived
  - Occasionally a long lived K^0 would decay into 2 pions
    - Means that long lived K^0 switched into a short lived K^0, violating CP

Cronin and Fitch Experiment

- Shot lived K^0 has CP of +1
- Long lived K^0 has CP of -1
- CP is violated when the long lived K^0 (CP= -1) decays like a short lived K^0 (CP= +1)



Foundations of the Six Quark Model

- Studied under Professor Shiochi Sakata and the Particle Physics group at Nagoya University
  - All 3 Nobel laureates from 2008 studied under Sakata
- Work of Sakata
  - Sakata Model- precursor to Quark model
  - MNS Matrix

Developments in Particle Physics

- 1950's- many new and strange particles discovered
  - "explosion" of particles
- 1956- Sakata Model
  - Hadrons are composite particles of triplets of p, n, Λ

β - decay $n \rightarrow p + e^- + \bar{\nu}$

strange paticle $\Lambda \rightarrow p + e^- + \bar{\nu}$

- 1962- discovery of a 2nd neutrino
  - Maki-Nakagawa-Sakata (MNS) matrix
  - 1st quantitative theory of neutrino oscillation

$$\nu_1 = \cos\theta\, \nu_e + \sin\theta\, \nu_\mu$$

$$\nu_2 = -\sin\theta\, \nu_e + \cos\theta\, \nu_\mu$$

Six Quark Model

- Sakata Model was replaced by a 3 quark model
  - Had flaws that made it incompatible with theory
- 4 quark model became preferable
  - However, it could not account for CP violation
- Kobayashi proposed the 6 quark model
  - One possible solution to the problem
  - Predicted the existence of unknown particles
- Similar model to the MNS matrix
  - Quark states are a superposition of each other

Six Quark Model

- Quark mixing matrix- Particles are a superposition of states
  - Irreducible complex #'s represent flavor mixing and CP violation

$$\begin{pmatrix} u \\ d' \end{pmatrix} \quad \begin{pmatrix} c \\ s' \end{pmatrix} \quad \begin{pmatrix} t \\ b' \end{pmatrix}$$

$$\begin{pmatrix} d' \\ s' \\ b' \end{pmatrix} = \begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \begin{pmatrix} d \\ s \\ b \end{pmatrix}$$

$$\begin{pmatrix} V_{ud} & V_{us} & V_{ub} \\ V_{cd} & V_{cs} & V_{cb} \\ V_{td} & V_{ts} & V_{tb} \end{pmatrix} \approx \begin{pmatrix} 1-\lambda^2/2 & \lambda & A\lambda^3(\rho - i\eta) \\ -\lambda & 1-\lambda^2/2 & A\lambda^2 \\ A\lambda^3(1-\rho-i\eta) & -A\lambda^2 & 1 \end{pmatrix}$$

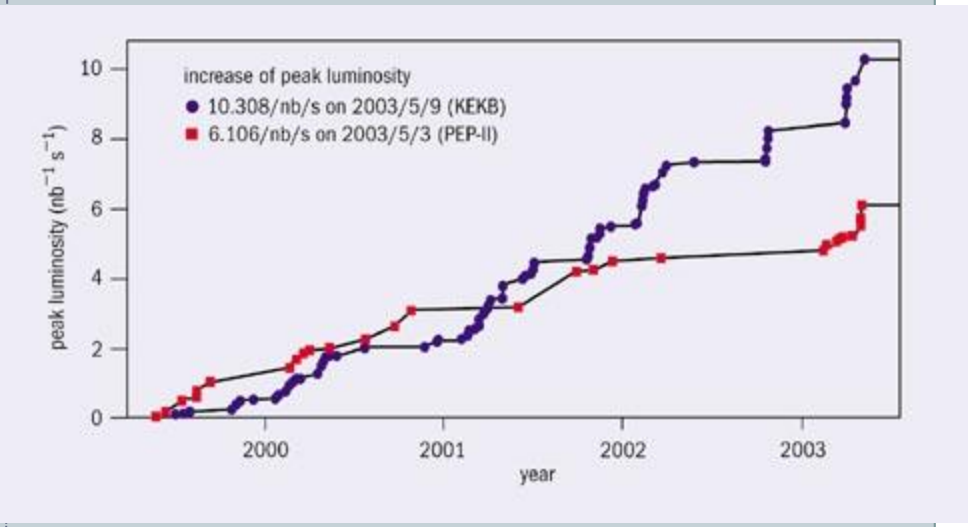
  - At the time, other proposed models had this similar properties
  - Experimental evidence needed to confirm the model

Discoveries

- 1974- J/ψ discovered
  - Bound state of the c, anti-c quarks
- 1975- τ lepton discovered
  - Suggested there should be a third family of quarks
- 1977- Upsilon particle discovered
  - Bound state of 5^{th} quark, the b and anti-b
- 1995- t quark discovered
  - 6^{th} and final quark

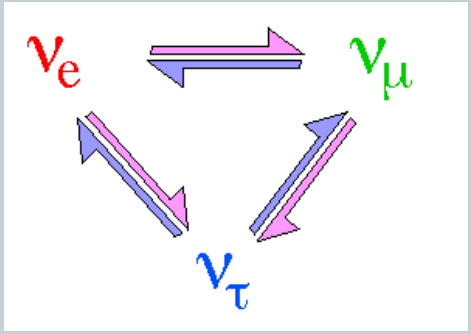
Experimental Confirmation

- B-factories
  - Accelerator that produces B-mesons
    - Pairs of quarks with either a b or anti-b quark
- Prediction of large asymmetry between b and anti-b
  - Find decay time by measuring its position by using a vertex detector
- KEKB accelerator in Japan and PEPII at SLAC
  - Great luminosities
  - Friendly competition



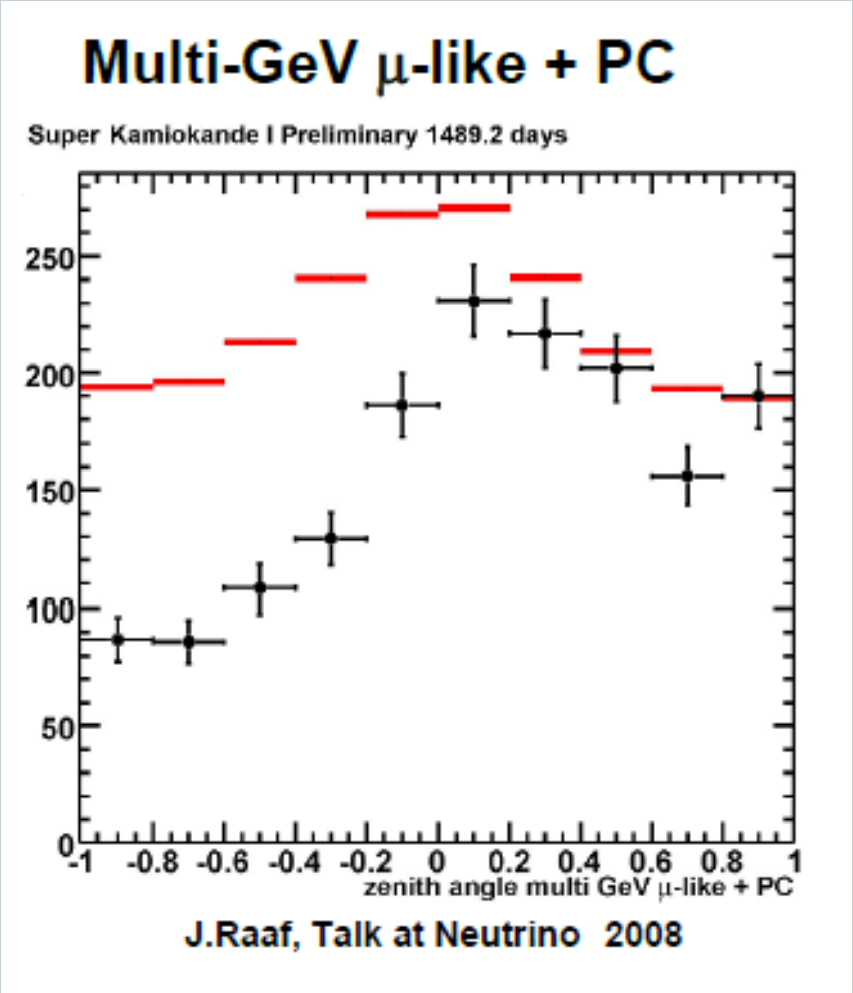
Results

- First experimental evidence of CP violation outside K^0 decays
- Quark mixing primary source of CP violation!!
  - Found an asymmetry between b and anti-b decays
- Room for new physics beyond standard model
- Need additional source of CP violation
  - Not enough to account for matter anti-matter asymmetry
- Lepton Flavor mixing



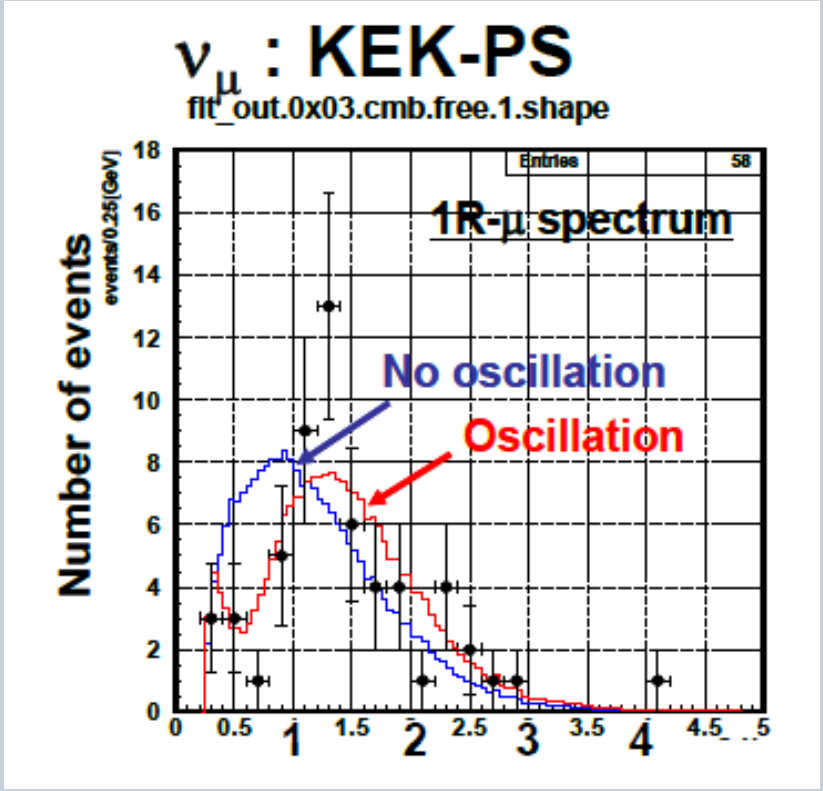
Lepton Flavor Mixing

- Super Kamiokande
  - Consistent with neutrino oscillation predictions
- KAMLand
  - Same observations
- Future experiments
  - T2K- similar to K2K but with higher intensities
  - $\upsilon_\mu \longrightarrow \upsilon_e$ oscillations
- Crucial for estimating size of CP violation from leptons

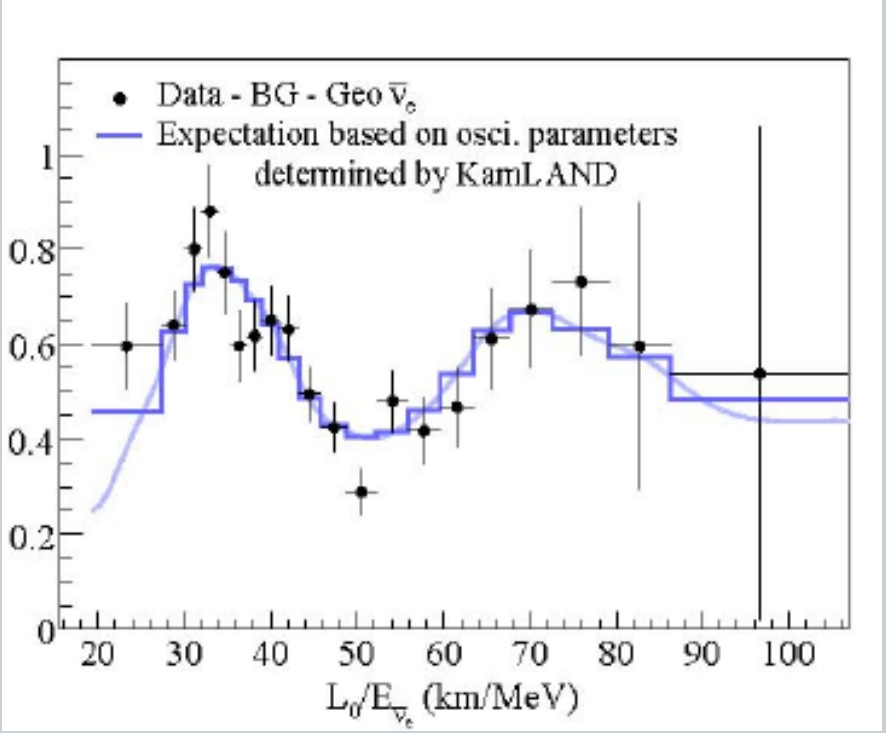


Experimental Results

K2K Data (υ_μ)



KAMLand Data (υe)



Conclusions

- 3 and 4 quark models did not allow for CP violation
- 6 quark model proposed by Kobayashi accounted for this
  - Experimental evidence to back it up
  - Particles that were discovered and from B-factories
- Need another source of CP violation
  - Lepton flavor mixing
- Hints of this from experiments already but more work is needed to be done

Experimental Results

-Colored circles and lines show experimental constraints from the matrix

-All overlap in one small region, colored red

-Can choose parameters in this region only

-6 quark model explains all the results for parameters in this region
